1 Some notes from which to expand this document

1. An overview of coupling proofs of privacy
2. A tight shift-coupling proof of privacy (segment free)
 - (a) What are the connecting constraints, and why are they there?
 - (b) Proofs have to depend on Δ !
 - (c) Proofs have to depend on sequences of segments!
3. Simplifying the problem above in various ways:
 - (a) Separability and the introduction of segments
 - (b) Only inter-segment transitions matter!
 - Given Δ , the γ values on inter-segment transitions are easily determined.
 - The Δ values on the inter-segment transitions can be determined.
4. Solving the problem.
 - (a) Hardness (incomplete)!!!
 - (b) Solving the easier version, where proofs don't depend on Δ .

(c) Showing that they are bounded within n of each other.

$$\exists \text{ finite DP bound} \iff \text{hard system admits a feasible solution}$$

3 Coupling proofs of privacy

A coupling proof of privacy

4 Shift-coupling proofs of privacy

Definition 4.1. Let $X = \langle a_1, \dots, a_m \rangle$ be an input, and $\rho = q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m$ be a path taken by DiPA \mathcal{A} on X . Define \tilde{a}_i to be the value of **insample** on the i th transition in ρ on input X .

,

Consider a path $\rho = q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m$. Consider inputs $X\langle 1 \rangle = \langle a_1\langle 1 \rangle, \dots, a_m\langle 1 \rangle \rangle$ and $X\langle 2 \rangle = \langle a_1\langle 2 \rangle, \dots, a_m\langle 2 \rangle \rangle$ such that $X\langle 1 \rangle \sim X\langle 2 \rangle$. We wish to show that there exists $\varepsilon \in (0, \infty)$ such that

$$\Pr [\rho | X\langle 1 \rangle] \leq \exp(\varepsilon) \cdot \Pr [\rho | X\langle 2 \rangle]$$

TODO: Write all of this later after consulting with Sky! ALSO, distinguish between path equivalence and output equivalence.

- The above is true if and only if $\text{path}_A(X) \Psi_\rho^{(\varepsilon, 0)} \text{path}_A(X')$, where

$$\Psi_\rho = \{(\rho_1, \rho_2) \in P \times P : \rho_1 = \rho \implies \rho_2 = \rho\}$$

Shift-couplings are a technique to show that $\text{path}_A(X) \Psi_\rho^{(\varepsilon, 0)} \text{path}_A(X')$ by constructing the couplings

$$\tilde{a}_i\langle 1 \rangle + \gamma_i(=)^{\#(\varepsilon_i, 0)} \tilde{a}_i\langle 2 \rangle \quad \forall i \in \{0, \dots, m-1\}$$

and showing that

$$(\tilde{a}\langle 1 \rangle + \gamma = \tilde{a}\langle 2 \rangle) \implies \text{path}_A(X\langle 1 \rangle) \Psi_\rho \text{path}_A(X\langle 2 \rangle)$$

thus showing that $\text{path}_A(X) \Psi_\rho^{(\varepsilon, 0)} \text{path}_A(X')$ for

$$\varepsilon = \sum_{i=0}^{m-1} \varepsilon_i$$

- A discussion that ends in choosing γ shifts for each segment.
- Maybe: A discussion of the cost of each shift.

4.1 Constraints

Definition 4.2. Given a fixed path, we say that an assignment of shifts $\{\gamma_i\}$ is **path-valid** if

$$(\tilde{a}\langle 1 \rangle + \gamma = \tilde{a}\langle 2 \rangle) \implies \text{path}_A(X\langle 1 \rangle) \Psi_\rho \text{path}_A(X\langle 2 \rangle)$$

Definition 4.3. Let $\rho = q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m$ be a path, and let $i \in \{1, \dots, m\}$. Define $\text{at}(i)$ to be the largest index $a(i) < i$ such that $\rho[a(i)] \rightarrow \rho[a(i) + 1]$ is an assignment transition.

Definition 4.4. Let $\rho = q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m$ be a path. Define t_i to be the transition $q_i \rightarrow q_{i+1}$.

Definition 4.5. Let $X = \langle a_1, \dots, a_m \rangle$ be an input, and let $\rho = q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m$ be a path. Define $X[i]$ to be the value of a_i .

Note that such an index must exist due to the initialization condition on DiPA.

Proposition 4.1. Given $\rho = q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m$, an assignment of shifts $\{\gamma_i\}$ is valid if and only if it satisfies the following constraints for all $i \in \{0, \dots, m-1\}$:

$$\begin{aligned} \gamma_i &\leq \gamma_{at(i)} && \text{if } t_i \text{ has guard } < \\ \gamma_i &\geq \gamma_{at(i)} && \text{if } t_i \text{ has guard } \geq \end{aligned}$$

Proof. (Constraints \implies valid) Suppose that the above constraints hold. We will show that $\{\gamma_i\}$ is valid using induction on $m = |\rho|$. Construct the couplings $\tilde{a}_i\langle 1 \rangle + \gamma_i(=)^{(\varepsilon_i, 0)} \tilde{a}_i\langle 2 \rangle$ for all $i \in \{0, \dots, m-1\}$.

For a base case, assume $m = 1$. Then ρ consists of an assignment transition t_0 with **true** guard (initialization condition). The constraints are trivially satisfied, and we have that $path_A(X\langle 1 \rangle) \Psi_\rho^{(0,0)} path_A(X\langle 2 \rangle)$.

Assume that the constraints hold for all paths of length m . Let $\rho = q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m \rightarrow q_{m+1}$. We will show that $\{\gamma_i\}$ is valid for ρ . First, by the validity of $\{\gamma_i\}_{i=0}^{m-1}$ for $\rho[0:m]$ by the inductive hypothesis, we have that

$$path_A(X\langle 1 \rangle) \Psi_{\rho[0:m]} path_A(X\langle 2 \rangle)$$

by the inductive hypothesis. Now, assume $path_A(X\langle 1 \rangle) = \rho$. We have $path_A(X\langle 2 \rangle)[0:m] = \rho[0:m]$. Consider the last transition t_m in ρ . Since $path_A(X\langle 1 \rangle) = \rho$, we know that t_m is traversed by A on $X\langle 1 \rangle$.

- If t_m has guard **true**, then we trivially have that $path_A(X\langle 2 \rangle) = \rho$.
- If t_m has guard $<$, we have from the constraints that $\gamma_m \leq \gamma_{at(m)}$. The value of the state variable $x\langle 1 \rangle$ is

$$x\langle 1 \rangle = \tilde{a}_{at(m)}\langle 1 \rangle$$

and since t_m is traversed by A on $X\langle 1 \rangle$, we have

$$\begin{aligned} \tilde{a}_m\langle 1 \rangle &< \tilde{a}_{at(m)}\langle 1 \rangle \\ \tilde{a}_m\langle 2 \rangle - \gamma_m &< \tilde{a}_{at(m)}\langle 2 \rangle - \gamma_{at(m)} \\ \tilde{a}_m\langle 2 \rangle &< \tilde{a}_{at(m)}\langle 2 \rangle - (\gamma_{at(m)} - \gamma_m) < \tilde{a}_{at(m)}\langle 2 \rangle \end{aligned}$$

showing that $\tilde{a}_m\langle 2 \rangle$ satisfies the guard of t_m . Thus, $path_A(X\langle 2 \rangle) = \rho$.

- If t_m has guard \geq , a similar argument as above shows that $path_A(X\langle 2 \rangle) = \rho$.

Thus, assuming that $a\langle 1 \rangle + \gamma = a\langle 2 \rangle$, we have shown that $path_A(X\langle 1 \rangle) = \rho \implies path_A(X\langle 2 \rangle) = \rho$, which shows $path_A(X\langle 1 \rangle) \Psi_\rho path_A(X\langle 2 \rangle)$, and so $\{\gamma_i\}$ is valid.

(Valid \implies constraints) Suppose that $\{\gamma_i\}$ is valid. Let $i \in \{0, \dots, m-1\}$. We will show that the constraints hold for i .

We will run the argument above in reverse. Again, we use induction on the length $m = |\rho|$. For a base case, assume $m = 1$, and so ρ consists of an assignment transition t_0 with **true** guard. The constraints are trivially satisfied, since there are none.

Assume that the constraints hold for all valid shift assignments on paths of length m , and let $\rho = q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m \rightarrow q_{m+1}$. Since $\{\gamma_i\}$ is valid for ρ , we have that $a\langle 1 \rangle + \gamma = a\langle 2 \rangle \implies path_A(X\langle 1 \rangle) \Psi_\rho path_A(X\langle 2 \rangle)$. Also, we have that $\{\gamma_i\}_{i=0}^{m-1}$ is valid for $\rho[0:m]$, and that constraints on transitions $t_i \in \rho[0:m]$ hold.

We will now show that the constraints on t_m hold by cases on the guard of t_m .

- If t_m has guard **true**, then there is no constraint on γ_m , and so the constraints hold.
- If t_m has guard $<$, the constraint to be shown is $\gamma_m \leq \gamma_{at(m)}$. Recall that we have $a\langle 1 \rangle + \gamma = a\langle 2 \rangle \implies \text{path}_A(X\langle 1 \rangle) \Psi_\rho \text{path}_A(X\langle 2 \rangle)$, showing that t_m being traversed by A on $X\langle 1 \rangle$ leads t_m to be traversed by A on $X\langle 2 \rangle$. Thus, we have

$$\begin{aligned}
\tilde{a}_m\langle 1 \rangle < \tilde{a}_{at(m)}\langle 1 \rangle &\implies \tilde{a}_m\langle 2 \rangle < \tilde{a}_{at(m)}\langle 2 \rangle \\
&\iff \tilde{a}_m\langle 1 \rangle + \gamma_m < \tilde{a}_{at(m)}\langle 1 \rangle + \gamma_{at(m)} \\
&\iff \tilde{a}_m\langle 1 \rangle < \tilde{a}_{at(m)}\langle 1 \rangle + (\gamma_{at(m)} - \gamma_m)
\end{aligned}$$

which is true if and only if $\gamma_m \leq \gamma_{at(m)}$. Thus, the constraint holds.

- A symmetric argument shows that the constraint holds if t_m has guard \geq .

Thus, the given constraints on γ hold if and only if it is valid for ρ . □

We can now reduce checking path-validity to checking the above constraints.

Definition 4.6. We say that γ is *output-valid* for ρ and Δ if we have

$$(\tilde{a}\langle 1 \rangle + \gamma = \tilde{a}\langle 2 \rangle) \implies \text{output}_A(X\langle 1 \rangle) \Psi_o \text{output}_A(X\langle 2 \rangle)$$

where

$$\Psi_o = \{(o_1, o_2) \in \mathcal{O}_\rho : o_1 = o \implies o_2 = o\}$$

where \mathcal{O}_ρ is the set of all outputs that can be produced by the path ρ .

Definition 4.7. Define \mathcal{P} to be the set of all paths in \mathcal{A} .

Note: we show that this is actually a proof after the next section.

Definition 4.8. Given a DiPA \mathcal{A} , a *shift-coupling proof of privacy* for \mathcal{A} is a map

$$\begin{aligned}
\Gamma : \mathcal{P} &\rightarrow ([-1, 1]^\rho \rightarrow [-1, 1]^{|\rho|}) \\
\rho &\mapsto (\Delta \mapsto \{\gamma_i\})
\end{aligned}$$

such that for all $\rho \in \mathcal{P}$ and all $\Delta \in [-1, 1]^\rho$, we have that $\{\gamma_i\}$ is valid for ρ and Δ , and satisfies the output constraints.

4.2 The cost of a shift-coupling

Proposition 4.2. Consider a transition $t_i = q_i \rightarrow q_{i+1}$ which is traversed independently by A on input $a_i\langle 1 \rangle$ and $a_i\langle 2 \rangle$. Let $\Delta_i = a_i\langle 2 \rangle - a_i\langle 1 \rangle$. Let q_i draw from the distribution $\text{Lap}(0, \varepsilon_i)$ to noise *insample*. The ε -cost of the coupling

$$\tilde{a}_i\langle 1 \rangle + \gamma_i(=)^{(c_i, 0)} \tilde{a}_i\langle 2 \rangle$$

is given by

$$c_i = |\Delta_i - \gamma_i| \varepsilon_i$$

Proof. TODO, but easy to see from coupling construction rules. □

Definition 4.9. Given a path ρ and input differences Δ , we define the ρ - Δ -**cost** of the shifts $\{\gamma_i\}$ to be

$$\text{cost}_\rho(\Delta, \{\gamma_i\}) = \sum_{i=0}^{|\rho|-1} |\Delta_i - \gamma_i| \varepsilon_i$$

Definition 4.10. Given a shift-coupling proof of privacy Γ , we define the privacy cost of Γ to be

$$\text{cost}(\Gamma) = \sup_{\rho \in \mathcal{P}} \sup_{\Delta \in [-1, 1]^\rho} \text{cost}_\rho(\Delta, \Gamma(\rho, \Delta))$$

4.3 Privacy

Theorem 1. Let \mathcal{A} be a DiPA, and Γ be a shift-coupling proof of privacy for \mathcal{A} with finite cost $\varepsilon = \text{cost}(\Gamma)$. Then, \mathcal{A} is $(\varepsilon, 0)$ -differentially private.

Proof. This is a direct consequence of output validity. □

4.4 Why the above had to be the way it is.

Since the total validity constraints on $\{\gamma_i\}$ does not depend on $X\langle 1 \rangle$ and $X\langle 2 \rangle$, one might be tempted to produce a proof of privacy by choosing γ_i to be the same for all $X\langle 1 \rangle$ and $X\langle 2 \rangle$, given a path ρ . Although this is possible, this does not in general produce a tight proof of privacy.

Proposition 4.3. (A tight proof must regard input differences) There exists a family of DiPA \mathcal{F} and for $\mathcal{A} \in \mathcal{F}$, a shift-coupling proof $\Gamma^* : \mathcal{P} \rightarrow ([-1, 1]^\rho \rightarrow [-1, 1]^{|\rho|})$ such that for all assignments $\Pi : \mathcal{P} \rightarrow [-1, 1]^\rho$ of paths to shifts, we have

$$\text{cost}(\Gamma^*) < \text{cost}(\Pi)$$

Proof. The construction is a DiPA with a one-segment path with same number of $<$ and \geq transitions. □

When constructing a shift-coupling proof of privacy, we are actually choosing a shift for each transition. Is it reasonable to ignore paths, and just choose a shift for each transition? The answer is no, as the following proposition shows.

Proposition 4.4. (A tight proof must regard paths) There exists a family of DiPA \mathcal{F} and for $\mathcal{A} \in \mathcal{F}$, a shift-coupling proof $\Gamma^* : \mathcal{P} \rightarrow ([-1, 1]^\rho \rightarrow [-1, 1]^{|\rho|})$ such that for all assignments $\Pi : E \rightarrow ([-1, 1]^\rho \rightarrow [-1, 1]^\rho)$ of transitions and differences to shifts, we have

$$\text{cost}(\Gamma^*) < \text{cost}(\Pi)$$

Proof. I have the counterexample written down, I found it by computer. Will write it up soon. □

5 The search for a tight proof as an optimization problem

5.1 Stating the problem abstractly

Now that we have a characterization of shift-coupling proofs of privacy, the problem of finding a tight proof of privacy can be formulated as finding, given ρ and Δ ,

$$\inf_{\Gamma} \text{cost}(\Gamma) = \inf_{\Gamma} \sup_{\rho} \sup_{\Delta} \text{cost}_\rho(\Delta, \Gamma(\rho, \Delta))$$

which is characterized by Γ^* such that for any shift-coupling proof Γ , we have

$$\sup_{\rho} \sup_{\Delta} \text{cost}(\Gamma^*(\rho, \Delta)) \leq \sup_{\rho} \sup_{\Delta} \text{cost}(\Gamma(\rho, \Delta))$$

One such Γ^* is the shift-coupling proof that chooses

$$\Gamma^*(\rho, \Delta) = \inf_{\gamma \in [-1, 1]^{|\rho|}} \text{cost}_{\rho}(\Delta, \gamma)$$

which is the shift-coupling proof that chooses the optimal shift for each input difference and path independently. We will now direct our focus to computing Γ^* given an automaton \mathcal{A} .

5.2 Simplifying the problem with fixed ρ, Δ

Proposition 5.1. *Let ρ, Δ be given, and let*

$$\gamma_i^* = \arg \inf_{\gamma \in [-1, 1]^{|\rho|}} \text{cost}_{\rho}(\Delta, \gamma)$$

For non-assignment transitions $t_i \in \rho$, we have that

$$\begin{aligned} \gamma_i^* &= \min(\Delta_i, \gamma_{at(i)}) && \text{if } t_i \text{ has guard } < \\ \gamma_i^* &= \max(\Delta_i, \gamma_{at(i)}) && \text{if } t_i \text{ has guard } \geq \end{aligned}$$

Proof. Missing, but I have notes for it. The proof comes from noting that shifts non-assignment transitions have only one linear constraint, and so we can solve for them optimally in terms of the shift on the previous assignment transition. \square

5.3 Simplifying the problem with fixed ρ

Proposition 5.2. *Let ρ be given. Let*

$$\Delta^* = \arg \sup_{\Delta \in [-1, 1]^{|\rho|}} \inf_{\gamma \in [-1, 1]^{|\rho|}} \text{cost}_{\rho}(\Delta, \gamma)$$

For non-assignment transitions $t_i \in \rho$, we have that

$$\Delta_i^* = \begin{cases} 1 & \text{if } t_i \text{ has guard } < \\ -1 & \text{if } t_i \text{ has guard } \geq \end{cases}$$

Proof. Missing, but I have notes for it. The proof goes by showing that the solution to the inner problem is at least as much as the solution to the inner problem with $\Delta_i = 1$ or $\Delta_i = -1$ respectively. \square

Corollary 1.1. *Let ρ be given. Let*

$$\Delta^* = \arg \sup_{\Delta \in [-1, 1]^{|\rho|}} \inf_{\gamma \in [-1, 1]^{|\rho|}} \text{cost}_{\rho}(\Delta, \gamma)$$

$$\gamma^* = \arg \inf_{\gamma \in [-1, 1]^{|\rho|}} \text{cost}_{\rho}(\Delta, \gamma)$$

As a consequence of Propositions 5.1 and 5.2, if $t_i \in \rho$ is a non-assignment transition, then

$$\gamma_i^* = \gamma_{at(i)}^*$$

The corollary above is important: it reveals that the only transitions that matter are assignment transitions!

5.3.1 Identifying segments

Corollary 1.1 allows us to formulate the problem of finding cost-minimal shifts γ over maximal input differences $\Delta \in [-1, 1]^{|\rho|}$ given ρ to the problem of finding γ and Δ for only the assignment transitions in ρ . This motivates the definition of a *segment* – a way of identifying paths in order to consider finitely many classes of paths.

Definition 5.1. Consider a DiPA \mathcal{A} . Let $q_i, q_j \in Q$ be such that there is a path $\rho = a_1 \rightarrow \dots \rightarrow a_m$ such that:

- $a_1 = q_i$ and $a_m = q_j$
- $a_1 \rightarrow a_2$ is the only assignment transition in ρ
- There exists an assignment transition out of q_j or it is a terminal state

Then we define $\text{seg}(q_i, q_j)$ to be the set of all paths from q_i to q_j that are acyclic with their first transition being their only assignment transition. We call such a path $s \in \text{seg}(q_i, q_j)$ a **segment**.

Definition 5.2. Given a segment $s \in \text{seg}(q_i, q_j)$, define the **segment family** $\text{segF}(s)$ to be the set of all paths ρ from q_i to q_j such that the only assignment transition in ρ is from q_i and $\text{acyclic}(\rho) = s$.

Proposition 5.3. Consider a path ρ with assignment transitions from states a_0, a_2, \dots, a_{n-1} , and terminal state a_n . There exists a unique sequence of segments $s_1 \hookrightarrow s_2 \hookrightarrow \dots \hookrightarrow s_n$ such we can write $\rho = \rho_1 \circ \rho_2 \circ \dots \circ \rho_n$ where $\rho_i \in \text{segF}(s_i)$ for all $i \in \{1, \dots, n\}$.

Proof. This is straightforward. □

Since we know from Corollary 1.1 that shifts on a segment are equal to the shift on the assignment transition of the segment, we need only consider pairs of $\Delta, \gamma \in \mathbb{R}$ for the assignment transition of the segment. From this, we can deduce the γ -minimal cost with respect to maximal Δ for any path in the segment family.

Definition 5.3. Given a path $\rho \in \text{segF}(s)$, we define the ρ -**segment cost** of s given γ, Δ to be

$$\rho\text{-segcost}_s(\Delta, \gamma) = \sum_{t_j \in \rho, t_j \in s} \text{cost}_\rho(\Delta, \gamma_j)$$

Definition 5.4. Let $s \in \text{seg}(q_i, q_j)$ be a segment, and let Δ and γ be input differences and shifts for all reachable transitions from s . Define the **segment cost** of s to be

$$\text{segcost}_s(\Delta, \gamma) = \sup_{\rho \in \text{segF}(s)} \rho\text{-segcost}_s(\Delta, \gamma)$$

Now, we can begin to formulate finding optimal Δ and γ for a path ρ as an optimization problem over segments.

Proposition 5.4. If a segment $s \in \text{seg}(q_i, q_j)$ has a cycle with a transition with guard $<$, then for $\Delta, \gamma \in \mathbb{R}$, we have

$$\text{segcost}_s(\Delta, \gamma) < \infty \iff \gamma = 1$$

Similarly, if s has a cycle with a transition with guard \geq , then for $\Delta, \gamma \in \mathbb{R}$, we have

$$\text{segcost}_s(\Delta, \gamma) < \infty \iff \gamma = -1$$

Proof. This follows from the fact that the $<$ transitions in a cycle have cost $|1 - \gamma|$, and \geq transitions in a cycle have cost $|(-1) - \gamma|$. There are paths in $\text{segF}(s)$ which make $\rho\text{-segcost}_s(\Delta, \gamma)$ arbitrarily large if these cyclic transitions are traversed with non-zero coupling cost. □

5.4 The optimization problem over segments

By Proposition 5.3, we can write any path ρ as a concatenation of paths each belonging to a segment family. Thus, our search for the tight shift-coupling bound

$$b = \sup_{\rho} \sup_{\Delta} \inf_{\gamma} \text{cost}(\Gamma^*(\rho, \Delta))$$

can be formulated as

$$\begin{aligned} & \max_{s^*} \max_{\Delta \in [-1,1]^n} \inf_{\gamma \in [-1,1]^n} \sum_{i=1}^n \text{segcost}_{s_i}(\Delta, \gamma) \\ & \text{subject to } G_{s^*}(\gamma) \geq 0 \end{aligned}$$

where s^* varies over all sequences of segments $s_1 \hookrightarrow s_2 \hookrightarrow \dots \hookrightarrow s_n$, and $G_{s^*} : \mathbb{R}^n \rightarrow \mathbb{R}^m$ encodes the set of constraints on γ given by the segments in s^* . In particular:

$$G_{s^*}(\gamma) = \begin{pmatrix} \gamma_i - \gamma_{i+1}, & \text{if } s_{i+1} \text{ has guard } < & \forall i \\ \gamma_{i+1} - \gamma_i, & \text{if } s_{i+1} \text{ has guard } \geq & \forall i \\ \gamma_i, & \text{if } s_i \text{ has a transition that outputs insample or insample} & \forall i \\ \gamma_i - 1, & \text{if } s_i \text{ has a cycle with a transition with guard } < & \forall i \\ -\gamma_i - 1 & \text{if } s_i \text{ has a cycle with a transition with guard } \geq & \forall i \end{pmatrix}$$

The first two constraints correspond to path validity, the third to output validity, and the last two to finiteness of the segment cost.

5.5 Solving the optimization problem over segments

Given a sequence of segments $s_1 \hookrightarrow s_2 \hookrightarrow \dots \hookrightarrow s_n$, we note certain properties about the optimization problem

$$\begin{aligned} & \max_{\Delta \in [-1,1]^n} \inf_{\gamma \in [-1,1]^n} \sum_{i=1}^n \text{segcost}_{s_i}(\Delta, \gamma) \\ & \text{subject to } G_{s^*}(\gamma) \geq 0 \end{aligned}$$

Proposition 5.5. *As a function of Δ , the inner problem*

$$\Delta \mapsto \inf_{\gamma \in [-1,1]^n} \sum_{i=1}^n \text{segcost}_{s_i}(\Delta, \gamma)$$

is strongly convex.

Proof. Segment costs are sums of absolute value functions and so are strongly convex, whose sum is convex. The pointwise infimum of convex functions is convex. \square

This shows that the optimization problem as stated is a convex maximization problem, which is NP-hard in general. Several attempts were made to solving this problem efficiently:

- Brute-force search over all $\Delta \in \{-1, 1\}^n$ and solving a linear program for $\gamma \in [-1, 1]^n$, which is computationally infeasible for large n . We can search for $\Delta \in \{-1, 1\}^n$ since convex functions take maxima at the vertices of their domain.
- Linear program sensitivity analysis – finding conditions on Δ that do not change optimal shifts for those Δ . Given $\gamma^* \in \{-1, 0, 1\}^n$ with $G_{s^*}(\gamma) \geq 0$, we use sensitivity analysis to find linear constraints on Δ for which

$$\gamma^* = \arg \inf_{\gamma} \sum_i \text{segcost}_{s_i}(\Delta, \gamma) \quad G_{s^*}(\gamma) \geq 0$$

This does not work in general as the number of feasible γ satisfying constraints given by G_{s^*} could be exponential in n , as shown by the following lemma:

Lemma 2. *For the constraints on γ of the form*

$$\gamma_1 \leq \gamma_2 \geq \gamma_3 \leq \dots \geq \gamma_n$$

there are $f(n-1)$ feasible γ satisfying the constraints, where $f(n)$ is the n th Fibonacci number.

No efficient solutions were found, and I suspect that the problem of finding maximal input differences with respect to minimal coupling shifts is NP-hard.

We will now present some bounds with respect to solutions to this optimization problem and solutions to a relaxed version of the problem.

6 A Relaxation and Linear-Time Decidability

6.1 Relaxing the optimization problem

Despite Proposition 4.3, we will now consider shift-coupling proofs of privacy that do not regard input differences, and investigate the tightness of such proofs.

Recall that a shift-coupling proof of privacy is a map

$$\begin{aligned} \Gamma : \mathcal{P} &\rightarrow ([-1, 1]^\rho \rightarrow [-1, 1]^{|\rho|}) \\ \rho &\mapsto (\Delta \mapsto \{\gamma_i\}) \end{aligned}$$

that assigns a shift to each path and sequence of input differences. We will consider shifts for which $\Gamma(\rho, \Delta)$ is constant for all Δ . We will call such a shift-coupling proof a **relaxed shift-coupling proof of privacy**.¹

The privacy bound afforded by such a proof is given by

$$\text{cost}(\Gamma) = \sup_{\rho \in \mathcal{P}} \sup_{\Delta \in [-1, 1]^\rho} \text{cost}_\rho(\Delta, \Gamma(\rho, \Delta))$$

We will now see what the search for a relaxed shift-coupling proof of privacy looks like.

Proposition 6.1. *Let ρ be given. Let*

$$\begin{aligned} \gamma^* &= \arg \inf_{\gamma \in [-1, 1]^{|\rho|}} \sup_{\Delta \in [-1, 1]^{|\rho|}} \text{cost}_\rho(\Delta, \gamma) \\ &\text{subject to } G_\rho(\gamma) \geq 0 \end{aligned}$$

and define $\Gamma^(\rho, \Delta) = \gamma^*$ for all Δ . Then, for all relaxed shift-coupling proofs of privacy Γ , we have $\text{cost}(\Gamma^*) \leq \text{cost}(\Gamma)$.*

¹I'm open to suggestions for a better name.

Proof. For fixed path ρ , we see that Γ^* has at most the cost of Γ on that path. This remains true when we take the supremum over all paths ρ . \square

Proposition 6.2. (*Relaxed shift-coupling proofs over segments*) *The search for a relaxed shift-coupling proof of privacy can be formulated as*

$$\begin{aligned} \max_{s^*} \quad & \inf_{\gamma \in [-1,1]^n} \sup_{\Delta \in [-1,1]^n} \sum_{i=1}^n \text{segcost}_{s_i}(\Delta, \gamma) \\ \text{subject to } & G_{s^*}(\gamma) \geq 0 \end{aligned}$$

where s^* varies over all sequences of segments $s_1 \hookrightarrow s_2 \hookrightarrow \dots \hookrightarrow s_n$, and $G_{s^*} : \mathbb{R}^n \rightarrow \mathbb{R}^m$ encodes the set of constraints on γ given by the segments in s^* .

Proof. Writing the problem over segments requires exactly the same steps as the formulation of the non-relaxed optimization problem over segments. The only difference is that we have switched γ and Δ . \square

Lemma 3. *For $\gamma \in [-1,1]$, we have that*

$$\sup_{\Delta \in [-1,1]} |\gamma - \Delta| = 1 + |\gamma|$$

Proof. Choosing $\Delta = -1 \cdot \text{sgn}(\gamma)$ shows that the supremum is at least $1 + |\gamma|$. To see that the supremum does not exceed $1 + |\gamma|$, use the triangle inequality. \square

Proposition 6.3. *For sequence of segments $s_1 \hookrightarrow s_2 \hookrightarrow \dots \hookrightarrow s_n$ and $\gamma \in [-1,1]^n$, we have that*

$$\arg \sup_{\Delta \in [-1,1]^n} \sum_{i=1}^n \text{segcost}_\rho(\Delta, \gamma) = -1 \cdot \text{sgn}(\gamma)$$

where $\text{sgn}(\gamma)$ is the vector with i th entry $\text{sgn}(\gamma_i)$, for which

$$\sum_{i=1}^n \text{segcost}_\rho(-1 \cdot \text{sgn}(\gamma), \gamma) = \sum_{i=1}^n \left((1 + |\gamma_i|) \varepsilon_i^0 + \sum_{t_j \in s_i, \text{guard}(t_j) = <} (1 - \gamma_i) \varepsilon_i^j + \sum_{t_j \in s_i, \text{guard}(t_j) = <} (1 + \gamma_i) \varepsilon_i^j \right)$$

where ε_i^j is the scale factor of the Laplace noise added to **insample** at transition t_j in segment s_i .

Proof. The main idea in the proof is that Δ is unconstrained, and each component Δ_i can be dealt with separately using Lemma 3. \square

We then see that we can find the minimum cost relaxed coupling shifts for a sequence of segments $s_1 \hookrightarrow s_2 \hookrightarrow \dots \hookrightarrow s_n$ by solving the following linear program with absolute values:

$$\begin{aligned} \min_{\gamma \in [-1,1]^n} \quad & \sum_{i=1}^n \text{segcost}_{s_i}(-1 \cdot \text{sgn}(\gamma), \gamma) \\ \text{subject to } & G_{s^*}(\gamma) \geq 0 \end{aligned}$$

since the objective function is linear in γ and $|\gamma|$. Further, the number of constraints is linear in n . Such programs can be solved using the simplex or ellipsoid methods. ²

²I am yet verifying that it meets the conditions for strongly polynomial solvability.

6.2 Closeness of relaxed shift-coupling proofs to tight shift-coupling proofs

We will now show that the cost of a relaxed shift-coupling proof of privacy is can be bounded in terms of the cost of a tight shift-coupling proof of privacy on a sequence of segments, and vice versa.

Theorem 4. *Let \mathcal{A} be a DiPA, and let Γ^* be an optimal shift-coupling proof of privacy. Let β^* be a relaxed shift-coupling proof of privacy with minimal cost. Consider a sequence of segments $s^* = s_1 \hookrightarrow s_2 \hookrightarrow \dots \hookrightarrow s_n$. Then, for any path ρ with $\text{acyclic}(\rho) = s^*$, we have*

$$\text{cost}_\rho(\Gamma^*) \leq \text{cost}_\rho(\beta^*) \leq \text{cost}_\rho(\Gamma^*) + \sum_{i=1}^n \varepsilon_{i,0}$$

Proof. We immediately have $\text{cost}_\rho(\Gamma^*) \leq \text{cost}_\rho(\beta^*)$ since Γ^* is the optimal shift-coupling proof of privacy. We will now show that $\text{cost}_\rho(\beta^*) \leq \text{cost}_\rho(\Gamma^*) + \sum_{i=1}^n \varepsilon_{i,0}$.

We can write

$$\begin{aligned} \text{cost}_\rho(\Gamma^*) &= \sup_{\Delta} \inf_{\gamma} \sum_{i=1}^n \text{segcost}_{s_i}(\Delta, \gamma) \quad \text{with } G_{s^*}(\gamma) \geq 0 \\ &= \sup_{\Delta} \inf_{\gamma} \sum_{i=1}^n (|\gamma_i - \Delta_i| \varepsilon_{i,0} + m_i \gamma_i + c_i) \quad \text{with } G_{s^*}(\gamma) \geq 0 \end{aligned}$$

for some $m_i, c_i \in \mathbb{R}$. Similarly,

$$\begin{aligned} \text{cost}_\rho(\beta^*) &= \inf_{\gamma} \sup_{\Delta} \sum_{i=1}^n \text{segcost}_{s_i}(\Delta, \gamma) \quad \text{with } G_{s^*}(\gamma) \geq 0 \\ &= \inf_{\gamma} \sum_{i=1}^n ((1 + |\gamma_i|) \varepsilon_{i,0} + m_i \gamma_i + c_i) \quad \text{with } G_{s^*}(\gamma) \geq 0 \end{aligned}$$

for the same $m_i, c_i \in \mathbb{R}$. Now, applying the reverse triangle inequality, we get that

$$\begin{aligned}
\sum_{i=1}^n (|\gamma_i - \Delta_i| \varepsilon_{i,0} + m_i \gamma_i + c_i) &\geq \sum_{i=1}^n ((|\gamma_i| - |\Delta_i|) \varepsilon_{i,0} + m_i \gamma_i + c_i) \\
&= \sum_{i=1}^n ((|\gamma_i|) \varepsilon_{i,0} + m_i \gamma_i + c_i) - \sum_{i=1}^n |\Delta_i| \varepsilon_{i,0} \\
&= \sum_{i=1}^n ((1 + |\gamma_i|) \varepsilon_{i,0} + m_i \gamma_i + c_i) - \sum_{i=1}^n (1 + |\Delta_i|) \varepsilon_{i,0} \\
\inf_{\gamma} \sum_{i=1}^n (|\gamma_i - \Delta_i| \varepsilon_{i,0} + m_i \gamma_i + c_i) &\geq \inf_{\gamma} \sum_{i=1}^n ((1 + |\gamma_i|) \varepsilon_{i,0} + m_i \gamma_i + c_i) - \sum_{i=1}^n (1 + |\Delta_i|) \varepsilon_{i,0} \quad \text{with } G_{s^*}(\gamma) \geq 0 \\
\sup_{\Delta} \inf_{\gamma} \sum_{i=1}^n (|\gamma_i - \Delta_i| \varepsilon_{i,0} + m_i \gamma_i + c_i) &\geq \sup_{\Delta} \left[\inf_{\gamma} \sum_{i=1}^n ((1 + |\gamma_i|) \varepsilon_{i,0} + m_i \gamma_i + c_i) - \sum_{i=1}^n (1 + |\Delta_i|) \varepsilon_{i,0} \right] \quad \text{with } G_{s^*}(\gamma) \geq 0 \\
&= \inf_{\gamma} \sum_{i=1}^n ((1 + |\gamma_i|) \varepsilon_{i,0} + m_i \gamma_i + c_i) - \sum_{i=1}^n \varepsilon_{i,0} \quad \text{with } G_{s^*}(\gamma) \geq 0 \\
&= \text{cost}_{\rho}(\beta^*) - \sum_{i=1}^n \varepsilon_{i,0}
\end{aligned}$$

finally showing that

$$\text{cost}_{\rho}(\beta^*) \leq \text{cost}_{\rho}(\Gamma^*) + \sum_{i=1}^n \varepsilon_{i,0}$$

□

This is a result that shows that the cost of a relaxed shift-coupling proof of privacy is close to the cost of a tight shift-coupling proof of privacy on a sequence of segments. This result is important because it allows us to bound the optimal shift-coupling cost in terms of the optimal relaxed shift-coupling cost, which is relatively easy to compute given a sequence of segments.

It also allows us to decide privacy by solving a simpler optimization problem. However, the next section shows that we can decide privacy in linear time without solving any optimization problems.

6.3 Deciding privacy in linear time

Theorem 5. *A DiPA \mathcal{A} is differentially private if and only if there exists a shift-coupling proof of privacy Γ with finite cost.*

Proof. This is one of Sky's theorems. □

Definition 6.1. *Define the **segment shift graph** of a DiPA \mathcal{A} to be the directed graph $G = (V, E)$ where:*

- *For every segment $s_i \in \text{seg}(\mathcal{A})$, there is a vertex $v_i \in V$ representing the coupling shift on the assignment transition of s_i .*
- *For every pair of segments (s_i, s_j) which have the connecting constraint $\gamma_i \leq \gamma_j$, there is an edge $(v_i, v_j) \in E$.*
- *There are nodes $\mathbf{1}, -\mathbf{1} \in V$ such that:*
 - *The only edge incident to $-\mathbf{1}$ is $(-\mathbf{1}, u)$ where u is the segment that initializes \mathcal{A} .*
 - *All terminal segments s_i have an edge $(v_i, \mathbf{1})$.*

Lemma 6. *Let there exist a path $v_1 \rightarrow \dots \rightarrow v_k$ in the segment shift graph of \mathcal{A} , and let the corresponding segments be s_{i_1}, \dots, s_{i_k} . Then we either have that*

$$s_{i_1} \hookrightarrow s_{i_2} \hookrightarrow \dots \hookrightarrow s_{i_k} \quad \text{and} \quad \text{guard}(s_{i_k}) = <$$

or

$$s_{i_k} \hookrightarrow s_{i_{k-1}} \hookrightarrow \dots \hookrightarrow s_{i_1} \quad \text{and} \quad \text{guard}(s_{i_k}) = \geq$$

Proof. We will use induction on k with base case $k = 2$. If we have $v_1 \rightarrow v_2$ in the segment shift graph, then we either have that $s_{i_1} \hookrightarrow s_{i_2}$ with $\text{guard}(s_{i_2}) = <$, or that $s_{i_2} \hookrightarrow s_{i_1}$ with $\text{guard}(s_{i_2}) = \geq$. For a path with length $k + 1$ in the segment shift graph, let us assume the desired result. Then apply the base case on $s_{i_k} \rightarrow s_{i_{k+1}}$ to conclude. \square

Theorem 7. *A DiPA \mathcal{A} is differentially private if and only if there does not exist a path from $\mathbf{1}$ to $-\mathbf{1}$ in the segment shift graph of \mathcal{A} .*

Proof. (\implies) Suppose that \mathcal{A} is differentially private. Then there exists a shift-coupling proof of privacy Γ with finite cost. Assume that there exists a path $\mathbf{1} \rightarrow v_1 \rightarrow \dots \rightarrow v_k \rightarrow -\mathbf{1}$ in the segment shift graph of \mathcal{A} . Without loss of generality, we have the sequence of segments $s_{i_1} \hookrightarrow \dots \hookrightarrow s_{i_k}$ corresponding to the path by Lemma 6. We can then extend this to a sequence of segments $s_1 \rightarrow \dots \rightarrow s_{i_1} \rightarrow \dots \rightarrow s_{i_k} \rightarrow \dots \rightarrow s_n$ that begins with the initialization segment and ends with a terminal segment.

If we restrict the segment-shift graph to only these segments, we find that any assignment of shifts γ would not be valid, as we would be able to construct a sequence of inequalities to conclude that $1 \leq -1$, which is false. Thus, there is no valid assignment of shifts γ for this sequence of segments with finite cost, and so Γ is not a shift-coupling proof of privacy with finite cost. This is a contradiction.

(\impliedby) This direction follows from the fact that there is *some* valid assignment of shifts γ with finite cost on each segment, and so we can construct a shift-coupling proof of privacy Γ with finite cost. \square

We can construct the segment shift graph of a DiPA in linear time, and check for a path from $\mathbf{1}$ to $-\mathbf{1}$ in linear time using a breadth-first search. Thus, we can decide privacy in linear time.

7 Do shift-coupling proofs of privacy have matching lower bounds?

Last Updated: Wednesday, June 28th, 2023

The relevant definitions and lemmata for proofs in this section are in the appendix. It is also assumed, for now, that all transition outputs are in the output alphabet.

7.1 S^L is tight when there is an L -cycle

Theorem 8. (S^L is tight for segments with L -cycles) *Consider a segment $s \in \text{seg}(\mathcal{A})$ corresponding to the sequence of states $q_0 \rightarrow q_1 \rightarrow \dots \rightarrow q_m$. If s contains an L -cycle, then the L -cost of the segment gives a tight upper bound on the privacy loss of the segment. That is,*

$$\text{loss}(s) = \exp \left(2\varepsilon_0 + \sum_{i>0: \text{guard}(a_i) = \text{insample} \geq x} 2\varepsilon_i \right)$$

given that state q_i draws from the distribution $\text{Lap}(0, 1/\varepsilon_i)$ to noise `insample`.

Proof. We will prove the result for when $\varepsilon_i = \varepsilon$ for all $i \geq 0$. The proof for the general case goes through in the same fashion. Let f, F be the probability density function and cumulative distribution function of a random variable X with $X \sim \text{Lap}(0, 1/\varepsilon)$ as defined in the appendix.

Since s has an L-cycle, there exists a sequence of paths ρ_i for $i \in \mathbb{N}$ each with l_i number of L-transitions such that $\lim_{i \rightarrow \infty} l_i = \infty$. Let m be the number of G -transitions in ρ_i . We will assume that this number is the same across all ρ_i .³

For each ρ_i , construct the adjacent pair of inputs X_i, X'_i as follows. Let $X_i[j] = 0$ for all $j \in \{1, \dots, |\rho_i|\}$, where $|\rho_i|$ is the number of transitions in ρ . Define $X_i[j]$ as follows:

$$X_i[j] = \begin{cases} 1 & \text{if } \rho_i[j] \rightarrow \rho_i[j+1] \text{ is an assignment transition or has guard } \mathbf{insample} \geq x \\ -1 & \text{otherwise, in which case } \rho_i[j] \rightarrow \rho_i[j+1] \text{ has guard } \mathbf{insample} < x \end{cases}$$

Let \tilde{a}_j be the random variable representing the value of **insample** before the j th transition in ρ on input X_i . Let \tilde{b}_j be the random variable representing the value of **insample** before the j th transition in ρ on input X'_i . Further, let $\Gamma_L = \{j : \rho_i[j] \rightarrow \rho_i[j+1] \text{ has guard } \mathbf{insample} < x\}$, and $\Gamma_G = \{j : \rho_i[j] \rightarrow \rho_i[j+1] \text{ has guard } \mathbf{insample} \geq x\}$.

Notice that $\tilde{a}_j = \tilde{b}_j + 1$ for $j \in \Gamma_L$, and $\tilde{a}_j + 1 = \tilde{b}_j$ for $j \in \{0\} \cup \Gamma_G$. Since \tilde{a}_j is distributed as $Lap(X_i[j], 1/\varepsilon)$, we can write its probability density function as $f(x - X_i[j])$, and its cumulative distribution function as $F(x - X_i[j])$. A similar statement holds for \tilde{b}_j .

We may now compute and compare $Pr(\rho_i|X'_i)$ and $Pr(\rho_i|X_i)$ as follows.

$$\begin{aligned} Pr(\rho_i|X'_i) &= \int_{-\infty}^{\infty} Pr(\tilde{b}_0 = x) \prod_{j \in \Gamma_L} Pr(\tilde{b}_j < x) \prod_{j \in \Gamma_G} Pr(\tilde{b}_j \geq x) dx \\ &= \int_{-\infty}^{\infty} Pr(\tilde{b}_0 = x) \prod_{j \in \Gamma_L} Pr(\tilde{b}_j < x) \prod_{j \in \Gamma_G} Pr(\tilde{b}_j \geq x) dx \\ &= \int_{-\infty}^{\infty} f_\varepsilon(x - X_i[0]) \prod_{j \in \Gamma_L} F_\varepsilon(x - X_i[j]) \prod_{j \in \Gamma_G} (1 - F_\varepsilon(x - X_i[j])) dx \\ &= \int_{-\infty}^{\infty} f(x - 1)F(x + 1)^{\ell_i}(1 - F(x - 1))^m \\ &= \int_{-\infty}^{\infty} f(x)F(x + 2)^{\ell_i}(1 - F(x))^m \\ &= \exp(2\varepsilon(m + 1)) \left(\int_{(-\infty, -2) \cup (2, \infty)} f(x)F(x)^{\ell_i}(1 - F(x))^m dx + g(\ell_i) \int_{-2}^2 f(x)F(x + 2)^{\ell_i}(1 - F(x))^m dx \right) \end{aligned}$$

with $g(\ell_i) \rightarrow 1$ as $\ell_i \rightarrow \infty$. As we take $\ell_i \rightarrow \infty$, we see that

$$h(\ell_i) := \frac{\left(\int_{(-\infty, -2) \cup (2, \infty)} f(x)F(x)^{\ell_i}(1 - F(x))^m dx + g(\ell_i) \int_{-2}^2 f(x)F(x + 2)^{\ell_i}(1 - F(x))^m dx \right)}{Pr(\rho_i|X_i)} \rightarrow 1$$

and so as we take the supremum over ρ_i below, we get:

$$\begin{aligned} \text{loss}(s) &\geq \sup_{\rho_i} \frac{Pr(\rho_i|X'_i)}{Pr(\rho_i|X_i)} = \exp(2\varepsilon(m + 1)) \sup_{\rho_i} \{h(\ell_i)\} \\ &= \exp(2\varepsilon(m + 1)) \end{aligned}$$

We know that S^L is tight, and gives the bound $\exp(2\varepsilon(m + 1))$. Thus, we have shown that $\text{loss}(s) = \exp(2\varepsilon(m + 1))$, as desired. \square

³Otherwise, s has a G-cycle, and \mathcal{A} is not differentially private. The privacy loss through s is ∞ , which matches the L -cost.

7.2 An alternative coupling strategy: S^J

Definition 7.1. S^J is a coupling strategy in which we do not couple the noised threshold, but couple the results of all other transitions with twice the cost. [TODO: Describe in more detail]

Theorem 9. Let $s = q_0 \rightarrow \dots \rightarrow q_m$ be a segment with only L -transitions. If S^J is the least-cost coupling strategy on s , then it provides a tight bound on $\text{loss}(s)$ given by

$$\text{loss}(s) = \sum_{i=1}^m 2\varepsilon_i$$

Proof. I have a proof for this, but I will add it into this document soon. [TODO]

Figure 1: A segment s with only L -transitions.

Figure 2:

Hypothesis 7.1. For segments which contain only L -transitions and for which the J -cost exceeds the L -cost, S^L is tight. □

Proof. I think this is true from the graph above, but I need to prove it.

Note June 28 2023: I think this is not true for segments that contain both L -transitions and G -transitions. □

A Lemmata

A.1 Properties of f_ε and F_ε

Lemma 10. For $x \leq 0$, we have

$$F_\varepsilon(x) = \exp(2\varepsilon)F_\varepsilon(x - 2)$$

and equivalently for $x \leq -2$, we have

$$F_\varepsilon(x + 2) = \exp(2\varepsilon)F_\varepsilon(x)$$

Lemma 11. For $x \geq 0$, we have

$$1 - F_\varepsilon(x) = \exp(2\varepsilon)(1 - F_\varepsilon(x + 2))$$

Lemma 12. For $x \geq 0$, we have

$$f_\varepsilon(x) = \exp(2\varepsilon)f_\varepsilon(x + 2)$$

A.2 For the proof of Theorem 1

Lemma 13.

$$\int_{-\infty}^{-2} f_\varepsilon(x) F_\varepsilon(x + 2)^\ell (1 - F_\varepsilon(x))^m dx = \exp(2\varepsilon\ell) \int_{-\infty}^{-2} f_\varepsilon(x) F_\varepsilon(x)^\ell (1 - F_\varepsilon(x))^m dx$$

Proof. From Lemma 10, we have that

$$\begin{aligned} \int_{-\infty}^{-2} f_\varepsilon(x) F_\varepsilon(x + 2)^\ell (1 - F_\varepsilon(x))^m dx &= \int_{-\infty}^{-2} f_\varepsilon(x) (\exp(2\varepsilon) F_\varepsilon(x))^\ell (1 - F_\varepsilon(x))^m dx \\ &= \exp(2\varepsilon\ell) \int_{-\infty}^{-2} f_\varepsilon(x) F_\varepsilon(x)^\ell (1 - F_\varepsilon(x))^m dx \end{aligned}$$

□

Lemma 14.

$$\int_0^\infty f_\varepsilon(x) F_\varepsilon(x + 2)^\ell (1 - F_\varepsilon(x))^m dx = \exp(2\varepsilon m) \int_2^\infty f_\varepsilon(x) F_\varepsilon(x)^\ell (1 - F_\varepsilon(x))^m dx$$

Proof. From Lemma 11 and 12, we have that

$$\begin{aligned} \int_0^\infty f_\varepsilon(x) F_\varepsilon(x + 2)^\ell (1 - F_\varepsilon(x))^m dx &= \int_0^\infty \exp(2\varepsilon) f_\varepsilon(x + 2) F_\varepsilon(x + 2)^\ell (\exp(2\varepsilon)(1 - F_\varepsilon(x + 2)))^m dx \\ &= \exp(2\varepsilon m) \int_0^\infty f_\varepsilon(x + 2) F_\varepsilon(x + 2)^\ell (1 - F_\varepsilon(x + 2))^m dx \\ &= \exp(2\varepsilon(m + 1)) \int_2^\infty f_\varepsilon(x) F_\varepsilon(x)^\ell (1 - F_\varepsilon(x))^m dx \end{aligned}$$

□

Lemma 15. There exists a function $g : \mathbb{N} \rightarrow \mathbb{R}$ such that

$$\int_{-2}^0 f_\varepsilon(x) F_\varepsilon(x + 2)^\ell (1 - F_\varepsilon(x))^m dx = g(\ell) \exp(2\varepsilon(m + 1)) \int_{-2}^2 f_\varepsilon(x) F_\varepsilon(x)^\ell (1 - F_\varepsilon(x))^m dx$$

with $g(\ell) \rightarrow 1$ as $\ell \rightarrow \infty$.

Proof. I'm not sure yet how to prove this, although I strongly suspect that the $(m + 1)$ term comes from the fact that $f_\varepsilon(x)$ is the derivative of $-(1 - F_\varepsilon(x))$, and it is taken to the m th power. Its integral should behave like a polynomial of degree $m + 1$ evaluated at 2, which corresponds to $\exp(2\varepsilon(m + 1))$. □
